## P14.1.3 [10 pts]

Suppose that  $M_1$  and  $M_2$  are two DFA's with the same input alphabet. We'll refer to the state set, start state, final state set, and transition function of  $M_1$  as  $S_1$ ,  $\iota_1$ ,  $F_1$ , and  $\delta_1$  respectively, and similarly for  $M_2$ . We define the **product DFA**  $M_1 \times M_2$  as follows. The state set is the direct product  $S_1 \times S_2$ , the set of ordered pairs  $\langle s_1, s_2 \rangle$  with  $s_1 \in S_1$  and  $s_2 \in S_2$ . The start state is the pair  $\langle \iota_1, \iota_2 \rangle$  and the final state set is  $F_1 \times F_2$ . The new transition function takes a state  $\langle s_1, s_2 \rangle$  and a letter  $a$  to  $\langle \delta_1(s_1, a), \delta_2(s_2, a) \rangle$ . Prove that the product DFA decides the language  $L(M_1) \cap L(M_2)$ .

### Solution:

solve using induction

base case: the languages are both the empty set so start state is also the end state, and our product DFA is equivalent to each M1 and M2 because it too is also empty

inductive hypothesis: for any string length  $n$ ;  $M_1 \times M_2$  decides the language  $L(M_1) \cap L(M_2)$

inductive step: suppose a non empty string  $w$  that is in the intersection of both languages, this means its accepted by M1 and M2; when processing  $w$ , M1 and M2 reach their respective final states which are in  $F_1 \times F_2$ , now suppose we have the same string but this time it ends in a letter  $a$ , which exists in  $F_1 \times F_2$  we do the same steps with  $w$  as before and get to  $s_1$ ,  $s_2$  which will be states just before the final state, and applying the transition function, we reach the DFA final state for both M1 and M2 and since  $w$  is accepted by both DFA it must be in the final states, proving that for each subsequent letter, there is a final state that can be reached if the string exists in both M1 and M2. this is spelling out the intersection of  $L(M_1) \cap L(M_2)$

### P14.2.5 [10 pts]

A string in  $\{a, \dots, z\}^*$  is said to be a **palindrome** if it is equal to its own reversal. Examples of palindromes are *madamimadam* and *ablewasiereisawelba*. Is the set of palindromes decidable by a DFA? Prove your answer.

#### Solution:

no there is not a DFA that can decide this, DFA is a finite state machine that must be able to be represented by a regular expression, but because these infinite length strings have no pattern for their first half (effectively random), which is effectively also infinite, but also need to match inversely in the second half, there is not a way to consider each of these patterns without a unique state for each one (they cannot be broken down into substrings), they cannot be represented using regular expressions, therefore cannot be represented using a DFA.

### P14.5.8 [10 pts]

The end of the section gives a recursive definition of the relation  $\Delta^*(s, w, t)$  in a  $\lambda$ -NFA for arbitrary states  $s$  and  $t$ , and arbitrary strings  $w$ . Prove by induction on this definition that if  $\Delta^*(s, w, t)$  is true, then there exists a path in the  $\lambda$ -NFA's state diagram from  $s$  to  $t$  such that the letter labels on the path, taken in order, spell out  $w$ .

#### Solution:

we can prove this with induction

base case: empty string,  $\Delta(s, \emptyset, t)$  where there is a path from  $s$  to  $t$  that consumes no input

hypothesis: for any string  $w$  with length  $n$ , if  $\Delta(s, w, t)$  is true then the path from  $s$  to  $t$  spells out  $w$

inductive step: if we use  $w = xa$  where  $x$  is a string length  $n$  and  $a$  is just the letter  $a$ , if  $\Delta(s, w, t)$  is true then there is a path from  $s$  to  $t$  that spells  $w$ . let's use  $y$  as an intermediate state in the path. by induction there must be a path from  $s$  to  $y$  that spells out  $x$ , also there must be one more edge that is  $a$  from  $y$  to  $t$ . therefore the entire path spells out  $xa$ , which is  $w$

## P14.6.4 [10 pts]

In Problem 14.3.4<sup>1</sup> we defined the language  $S = \Sigma^* a \Sigma^k$  of strings whose  $k+1$ 'st to last letter exists and is  $a$ . (Here  $k$  is an arbitrary natural.) Design an NFA for this language with  $k+2$  states and apply the Subset Construction to it. Minimize your DFA if necessary. You now have an example that will prove a theorem of the following form: For every  $n$  with  $n \geq n_0$ , there exists a language that has an  $n$ -state ordinary NFA and whose minimal DFA has  $f(n)$  states. You get to pick  $n_0$ , and the function  $f(n)$  should be as large as you can make it.<sup>2</sup>

### Solution:

create the NFA  $M$

there will be  $k+2$  states  $s_0 s_1 s_2 \dots s_{k+1}$

$s_0$  will loop on reading an  $a$  or  $b$ , and move onto  $s_1$  on reading an  $a$

$s_n$  will move to  $s_{n+1}$  on reading a letter in  $\Sigma$  for  $1 \leq n \leq k$

$s_{k+1}$  is the final state with no outgoing transitions and only a pointing in

converting the NFA  $M$  to a DFA  $M'$  using subset construction

1. Initial State: let's denote the start state/ input state as  $s_0$
2. Transitions: combining equivalent states, we find that most of the states do the same thing, loop on  $a$  or  $b$  and move on with  $a$ , so we only need 2 nodes to represent, moving to the end state on  $a$ , and looping on  $b$ , for the other node we loop on  $a$  and move back to start state on  $b$
3. Final State: any string that terminates on the final state (1) in the figure

---

<sup>1</sup>Let  $k$  be a natural, let  $\Sigma = \{a, b\}$ , and consider the regular language  $S_k = \Sigma^* a \Sigma^k$ , consisting of all those strings whose  $k+1$ 'st to last letter exists and is an  $a$ . Find the minimal DFA for each such language  $S_k$ , and prove that it is minimal.

<sup>2</sup>Please check Piazza @996 for some additional notes on the problem.

### P14.7.5 [10 pts]

Here is another way to modify a  $\lambda$ -NFA. For every letter move  $\langle s, x, t \rangle$ , where  $x$  is a letter in  $\Sigma$ , add a corresponding  $\lambda$ -move  $\langle s, \lambda, t \rangle$ . Keep the start state and final state set the same.

- (a) Describe a three-state ordinary NFA whose language is  $\{ab\}$ . Apply this modification to your NFA and describe the result. What is the language of the modified  $\lambda$ -NFA?
- (b) If this modification is applied to a  $\lambda$ -NFA with language  $L$ , what is the resulting language?

#### Solution:

- (a) to find out the language we need to consider all possible paths, but because the lambda steps skip the letter, the language is now  $a+b+ab$

- (b) if this modification is applied to a  $\lambda$ -NFA with language  $L$ , each transition state can be skipped therefore the empty set, each individual letter, and all combinations of letters in the same order, with just deletions will be in  $L$ , for example if  $L = abc$  in that order, then there will be  $a, b, c, ab, ac, bc, abc$  in the new set

### P14.8.9 [10 pts]

Formally prove the correctness of our construction for the star operator, as follows. Let  $N$  be a  $\lambda$ -NFA constructed for the regular expression  $\alpha$ , and let  $N'$  be the one constructed for  $\alpha^*$ , with two new states and four new  $\lambda$ -moves. Let  $L$  be the language of  $\alpha$ .

- (a) By induction on all naturals  $t$ , prove that if  $w$  is any string in the language  $L^t$ , then there are  $w$ -paths from the start state of  $N'$  to both the original final state of  $N$  and to the final state of  $N'$ . (The path to  $N$ 's final state is a useful inductive hypothesis.)
- (b) Prove, by induction on all paths from the start state of  $N'$  to either the original start state of  $N$ , the original final state of  $N$ , or the final state of  $N'$ , that the string read on the path is in the language  $L^*$ .

#### Solution:

- (a) base case:  $t = 0$ , where  $L$  will be the empty set,  $w$  will be length 0 and  $N$  &  $N'$  will be also length 0  
inductive hypothesis: if  $w$  is any string in the language  $L^t$ , then there are  $w$ -paths from the start state of  $N'$  to both the original final state of  $N$  and to the final state of  $N'$ .  
inductive step: let  $w$  be any string in  $L^{k+1}$  which can be expressed as  $xy$  where  $x$  is a string in  $L^k$  and  $y$  is a string in  $L$ , using the hypothesis we already know that there exists  $x$  paths from start of  $N'$  to both original final state in  $N$  and final state of  $N'$ , also since  $Y$  is in  $L$  there exists a path  $y$  from the start state of  $N'$  to the final state of  $N'$ . concatenating these paths we can create  $w$  paths from the start state of  $N'$  to both the original final state  $N$  and the final of  $N'$
- (b) same base case, meaning that the empty string exists in  $L$ , also we utilize the previous inductive step, which already state for an  $k$ , if  $w$  is in  $L^k$  there is  $w$  paths from the start state of  $N'$  to both the original final state of  $N$  and the final state of  $N'$

## P14.10.2 [10 pts]

Build successively a  $\lambda$ -NFA, an NFA, a DFA, and a minimal DFA from the regular expression in Exercise 14.10.3<sup>3</sup>. Before making the ordinary NFA, simplify the  $\lambda$ -NFA to an equivalent one with six states, using loops for the  $a^*$  components.

Note: We will give you the  $\lambda$ -NFA to start with.

Figure 1:  $\lambda$ -NFA for  $(b + ab^*ab^*a)^*$

**Solution:**

Figure 2: NFA & DFA for  $(b + ab^*ab^*a)^*$

states 2 and 3 are equivalent so combine them, 1 and 4 are also equivalent so combine them

<sup>3</sup>Design a DFA whose language is the set of strings in  $\{a, b\}^*$  that have a number of  $a$ 's divisible by 3. Use the state elimination construction to obtain a regular expression for this language.

Figure 3: Minimized DFA for  $(b + ab^*ab^*a)^*$

## EC: P14.10.10 (a, b) [10 pts]

In Problem 5.5.1<sup>4</sup> we defined the **quotient** of a language  $L$  by a letter  $a$ , so that the language  $La^{-1}$  was defined to be the set  $\{w : wa \in L\}$ . We proved there that we could take a regular expression  $\alpha$  and produce a regular expression for  $L(\alpha)a^{-1}$ .

- (a) The quotient of a language  $L$  by a string  $w$  is the set  $Lw^{-1} = \{u : uw \in L\}$ . Argue using the result of Problem 5.5.1 that  $Lw^{-1}$  must be regular if  $L$  is regular and  $w$  is any string.
- (b) Let  $D$  be a DFA for a language  $L$  and let  $w$  be any string over  $D$ 's alphabet. Argue that there is a DFA  $D'$ , whose language is  $Lw^{-1}$ , that can be obtained from  $D$  by simply changing the final state set.

**Solution:**

---

<sup>4</sup>If  $L$  is a language and  $a$  is a letter, we define the **quotient of  $L$  by  $a$** , written  $La^{-1}$ , as follows.  $La^{-1}$  consists of all those strings that *would be* in  $L$  if you appended an  $a$  to them — formally,  $La^{-1} = \{w : wa \in L\}$ . Prove that if  $S$  is any regular expression, and  $a$  is any letter, then  $L(S)a^{-1}$  is a regular language. Give a recursive algorithm to produce a regular expression for this language.

### EC: P15.6.1 [10 pts]

Build a Turing machine  $M_{shift}$  that when started on input  $w$  (i.e., in configuration  $\iota \sqcup w$ ), halts with tape contents  $\sqcup \sqcup wh \sqcup$ . Let  $\Sigma = \{a, b\}$ .

**Solution:**
